

Low Carbon Vehicle Partnership Annual Conference, 8th July 2019
Neville Hargreaves

Altalto waste-to-jet-fuel project

Hydrocarbon fuels and alternatives

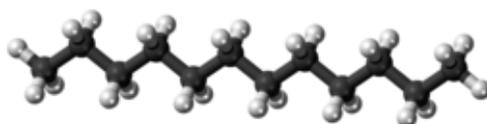

Petrol /
gasoline

- 4-12 carbon atoms
- Substitute: ethanol from fermentation of sugars

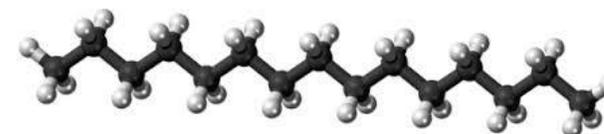

Jet fuel /
kerosene

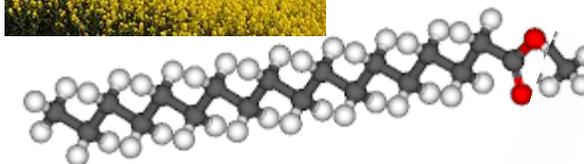

- 8-15 carbon atoms
- Substitute: needs to be essentially the same chemical substances
 - Energy density
 - Water shedding
 - Freeze point -47°C

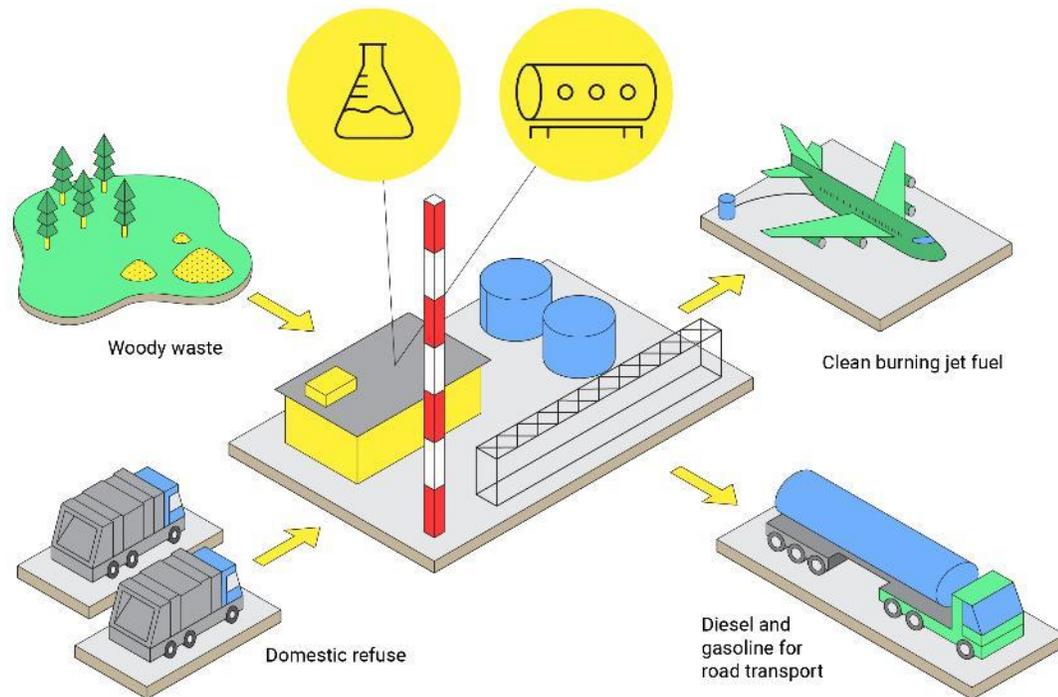

Diesel

- 10-20 carbon atoms
- Substitute: fatty acid esters from vegetable (e.g. rapeseed) oils

Fischer Tropsch route to sustainable fuels

- Clean paraffinic fuel
 - 90% reduction in key exhaust pollutants (particulate matter, sulphur)
 - Approved at up to 50% in blend (ASTM D7566)
 - No changes to engines or infrastructure
- Greenhouse gas (GHG) reduction ~70%
 - Could be >100% with carbon capture
- Large resources of waste feedstock
 - Better (lower net GHG) way to dispose of residual waste than landfill or incineration

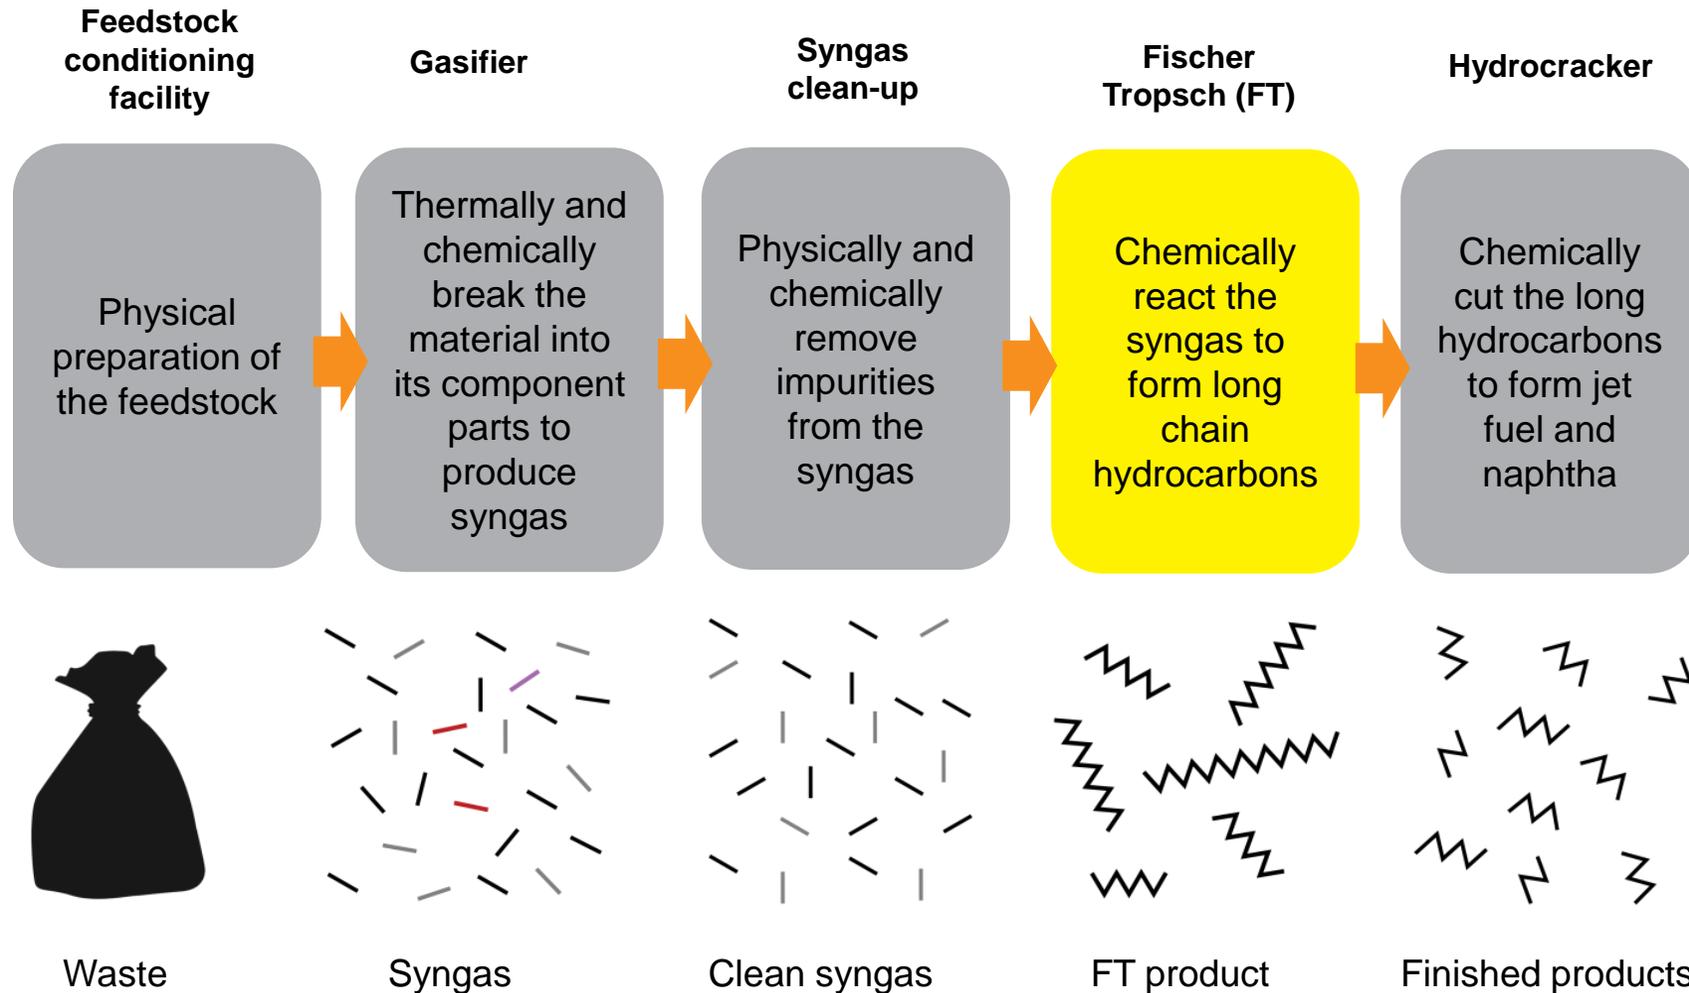

Product burns more cleanly than conventional fuel...
...as well as the greenhouse gas savings

Left: Diesel made using Velocys process; right: diesel from filling station

Process overview

Using established technologies

Velocys provides technology, integration and development

- Technology demonstrated at commercial scale
 - Reactor and catalyst for hydrocarbon synthesis (jet, diesel, naphtha)
- Combined with proven gasification, purification and hydrocracking technologies in end-to-end process
- Expert team with experience of designing, commissioning and operating synthetic fuel facilities
 - UK and US
- Traded on AIM (ticker: VLS)

ENVIA plant in Oklahoma City: commercial-scale demonstration of Velocys technology

ALTO

Project to build UK commercial waste-to-jet-fuel plant

60 million
litres of clean
drop-in fuel
(for jet and
petrol)

500,000
tonnes of
residual waste
saved from
landfill

Site near Immingham

- Vacant land with industrial neighbours – earmarked for development under Local Plan
- Good transport and utility connections
- Energy Estuary renowned for fuels production expertise and highly skilled local workforce

Project status

- £5 million invested in current stage including £434k F4C Stage One grant¹
- Site selected, planning consultation in progress
- Plan to start construction 2021 subject to planning and funding

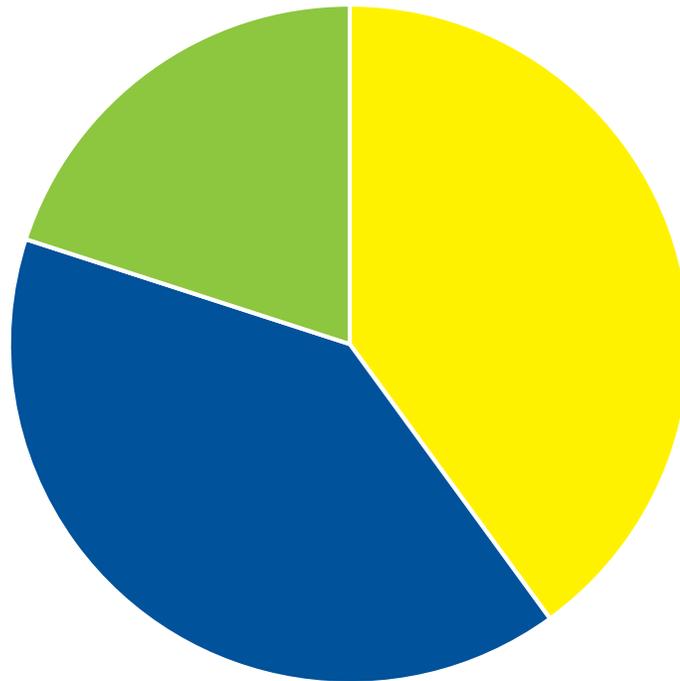

¹ F4C is the Future Fuels for Flight and Freight Competition, funded by the Department for Transport

Model of plant on site near Immingham, North East Lincolnshire, UK

Transport fuels policy key to early sustainable fuels plants

Typical revenue sources

- Waste treatment fees
- Renewable Transport Fuel Certificates
- Base fuels value

- In 2018, changes to Renewable Transport Fuel Obligation passed into law
 - Awards higher-value certificates for “Development Fuels”
 - Includes aviation fuel
 - For now, only credits in proportion to biogenic fraction of waste
- Combination of revenue streams required to make economics work

Summary

- Aviation is the most difficult transport sector for GHG reduction
 - Marine and heavy goods also challenging
- Fischer-Tropsch route gives:
 - 70% GHG reduction
 - 90% reduction in key exhaust pollutants
 - Better treatment of municipal waste
- Commercial project in development in Immingham with British Airways and Shell
